

Les complications cardiovasculaires VI

- Les études contemporaines
- Les controverses
 - Théorie du cholestérol
- Les nouveaux facteurs de risque (non pris en considération dans les scores)
 - Tabagisme passif
 - Pollution atmosphérique
 - Stress
 - Horaires de travail long
 - IMC à l'adolescence
 - Origine développementale
 - Médicaments
 - Syndrome d'apnées obstructives du sommeil (SAS)
 - Covid

Remarques importantes

- Le **style de vie a changé** depuis le début de l'étude de Framingham.
- Des **facteurs de risque majeurs et des interventions majeures ont été ignorés** comme le tabagisme passif ou le type d'alimentation (régime méditerranéen).
- Les **études se concentrent sur une intervention isolée** (et non sur une prescription globale).
- Il faudrait disposer de nouvelles études correspondant à des **populations contemporaines intégrant les mesures prises au niveau de la société (vraie prévention primaire)**.

Les rares études « contemporaines »

Méthodologie de l'ECR

- **Hommes** de 65 à 74 ans vivant dans 15 municipalités danoises
- Dépistage : tomодensitométrie avec électrocardiographie sans contraste pour déterminer le score de calcium de l'artère coronaire et pour détecter les anévrismes et la fibrillation auriculaire, mesures de la pression artérielle cheville-bras pour détecter la maladie artérielle périphérique et l'hypertension, échantillon de sang pour détecter le diabète sucré et l'hypercholestérolémie.
- Critère de jugement principal : décès quelle qu'en soit la cause

Etude contemporaine

Septembre 2014 à septembre 2017

Table 1. Definitions of Positive Findings and Recommended Preventive Actions.*

Criteria for Positive Finding	Recommended Action
Increased coronary-artery calcification (coronary-artery calcium score greater than the median sex- and age-specific score)	Provide recommendations regarding general cardiovascular prevention† Provide referral to cardiology department if angina pectoris is suspected
Ascending aortic aneurysm ≥ 45 mm in maximal diameter at the site where the anterior-posterior and transverse diameters are equivalent on axial CT	Provide recommendations regarding general cardiovascular prevention† If ≥ 55 mm, provide referral for surgical evaluation If ≥ 50 mm, perform echocardiography to detect bicuspid aortic valve; if not detected, perform annual control CT, and if detected, provide referral for surgical evaluation If 45–49 mm, assess with CT after 5 yr
Aortic arch aneurysm ≥ 40 mm on axial CT	Provide recommendations regarding general cardiovascular prevention† If ≥ 55 mm, provide referral for surgical evaluation If < 55 mm, perform annual control CT
Descending aortic aneurysm ≥ 35 mm on axial CT	Provide recommendations regarding general cardiovascular prevention† If ≥ 55 mm, provide referral for surgical evaluation If 45–54 mm, perform annual control CT If 35–44 mm, perform control CT every second yr
Abdominal aortic aneurysm ≥ 30 mm on axial CT	Provide recommendations regarding general cardiovascular prevention† If ≥ 55 mm, provide referral for surgical evaluation If 50–54 mm, perform control CT twice a year If 45–49 mm, perform annual control CT If 30–44 mm, perform control CT every second yr

Iliac aneurysm ≥ 20 mm on axial CT	Provide recommendations regarding general cardiovascular prevention† If ≥ 35 mm, provide referral for surgical evaluation If 30–34 mm, perform annual control CT If 20–29 mm, perform control CT every second yr
Peripheral artery disease (ankle–brachial blood-pressure index value ≤ 0.90 or > 1.40)	Provide recommendations regarding general cardiovascular prevention† Provide instructions regarding walking exercise Provide referral to vascular surgical department if critical limb ischemia suspected because of pain at rest, ulcers, or gangrene
Atrial fibrillation (irregular rhythm on ECG-gated monitor)	Confirm by 12-lead ECG If not confirmed, no action If confirmed, provide referral for cardiac evaluation and initiate anticoagulant medication (unless contraindicated)
Potential hypertension (systolic blood pressure ≥ 160 mm Hg or diastolic blood pressure ≥ 100 mm Hg)	Provide referral to general practitioner for confirmation and treatment
Suspected diabetes mellitus (glycated hemoglobin level ≥ 48 mmol/mole)	Provide referral to general practitioner for confirmation and treatment
Hypercholesterolemia (total cholesterol level ≥ 8.0 mmol/liter)	Provide referral to general practitioner for confirmation and treatment

Table 2. Baseline Characteristics of the Participants.*

Characteristic	Control Group (N=29,843)	Invited Group (N=16,768)	Unscreened Invited Participants (N=6297)	Screened Invited Participants (N=10,471)
Mean age — yr	68.8±2.6	68.8±2.6	68.9±2.7	68.7±2.6
Education after primary school — no. (%)				
None	7849 (26.3)	4331 (25.8)	2057 (32.7)	2274 (21.7)
<3 yr	15,265 (51.2)	8577 (51.2)	3009 (47.8)	5568 (53.2)
≥3 yr	6676 (22.4)	3828 (22.8)	1201 (19.1)	2627 (25.1)
Missing data	53 (0.2)	32 (0.2)	30 (0.5)	2 (0.1)
Currently working — no. (%)	7577 (25.4)	4288 (25.6)	1327 (21.1)	2961 (28.3)
Non-Danish ethnic group — no. (%)	1235 (4.1)	641 (3.8)	341 (5.4)	300 (2.9)
Prescriptions within 1 yr before randomization — no. (%)				
Antiplatelet agents	7617 (25.5)	4191 (25.0)	1695 (26.9)	2496 (23.8)
Anticoagulant agents	2589 (8.7)	1444 (8.6)	600 (9.5)	844 (8.1)
Lipid-lowering agents	11,458 (38.4)	6261 (37.3)	2289 (36.4)	3972 (37.9)
Antihypertensive agents	15,787 (52.9)	8759 (52.2)	3418 (54.3)	5341 (51.0)
Antidiabetic agents	3777 (12.7)	2167 (12.9)	1039 (16.5)	1128 (10.8)
Reason for hospital admission within 5 yr before randomization — no. (%)				
Stroke	1531 (5.1)	751 (4.5)	346 (5.5)	405 (3.9)
Ischemic heart disease	1230 (4.1)	638 (3.8)	233 (3.7)	405 (3.9)
Peripheral artery disease	647 (2.2)	374 (2.2)	192 (3.0)	182 (1.7)
Aortic aneurysm	450 (1.5)	279 (1.7)	130 (2.1)	149 (1.4)

Table 3. Primary and Secondary Outcomes.*

Outcome	Control Group (N=29,843)			Invited Group (N=16,768)			Hazard Ratio (95% CI)	P Value
	Participants with Event	Median Yr at Risk (IQR)	Events/1000 Person-Yr	Participants with Event	Median Yr at Risk (IQR)	Events/1000 Person-Yr		
	no. (%)		no.	no. (%)		no.		
Primary outcome: death from any cause

Major amputation	143 (0.5)	5.6 (4.8–6.2)	0.9	85 (0.5)	5.6 (4.9–6.2)	1.0	1.05 (0.80–1.38)	

* For age-stratified and secondary outcomes, the widths of the confidence intervals were not adjusted for multiplicity, so the intervals should not be used in place of a hypothesis test. IQR denotes interquartile range.

No. at Risk

Unscreened participants	29,790	29,242	28,552	27,907	27,182	19,712	10,409
Screened participants	16,736	16,390	16,072	15,720	15,330	11,591	5,837

Figure 1. Cumulative Incidence of Death from Any Cause.

The shaded areas represent 95% confidence intervals. The inset shows the same data on an enlarged y axis.

Conclusion

Après plus de 5 ans, l'invitation à subir un dépistage cardiovasculaire complet n'a pas réduit significativement l'incidence des décès toutes causes confondues chez les hommes de 65 à 74 ans.

Exemple 2 : Sténose carotidienne asymptomatique

Carotid endarterectomy or stenting or best medical treatment alone for moderate-to-severe asymptomatic carotid artery stenosis: 5-year results of a multicentre, randomised controlled trial

*Tilman Reiff, Hans-Henning Eckstein, Ulrich Mansmann, Olav Jansen, Gustav Fraedrich, Harald Mudra, Dittmar Böckler, Michael Böhm, E Sebastian Debus, Jens Fiehler, Klaus Mathias, Erich B Ringelstein, Jürg Schmidli, Robert Stingeles, Ralf Zahn, Thomas Zeller, Wolf-Dirk Niesen, Kristian Barlinn, Andreas Binder, Jörg Glahn, Werner Hacke, Peter Arthur Ringleb, for the SPACE-2 Investigators**

Summary

Background The optimal treatment for patients with asymptomatic carotid artery stenosis is under debate. Since best medical treatment (BMT) has improved over time, the benefit of carotid endarterectomy (CEA) or carotid artery stenting (CAS) is unclear. Randomised data comparing the effect of CEA and CAS versus BMT alone are absent. We aimed to directly compare CEA plus BMT with CAS plus BMT and both with BMT only.

Lancet Neurol 2022; 21: 877–88

Data are number of events (cumulative incidence % [95% CI]). Death, vascular death, and myocardial infarction events were counted from after randomisation. All other outcome events were counted from after randomisation for BMT or from after the intervention for either CEA or CAS. CEA=carotid endarterectomy. CAS=carotid artery stenting. BMT=best medical treatment. *Log-rank test for equality of survivor functions. †modified Rankin Scale score >2 at 30 days after stroke. ‡One patient who underwent CAS had both secondary endpoint events (stroke and later death) but was counted only once. §Reported according to European Carotid Surgery Trial criteria. ¶Re-stenosis only in the CEA and CAS groups. Re-stenosis only in the CEA and CAS groups and progressive stenosis only in the BMT group. **Exploratory analysis.				
Table 2: Kaplan-Meier estimates of cumulative incidence of outcome events within 5 years				

Figure 2: Cumulative incidence of primary endpoint events within 5 years

Kaplan-Meier plots show the cumulative incidence within 5 years of primary endpoint events (A), ipsilateral ischaemic stroke (B), any ischaemic or haemorrhagic stroke (C), and all-cause death (D). Time to event in parts A–C was calculated after intervention in patients treated with CEA or CAS and after randomisation in patients treated with BMT. Time to event in part D was calculated after randomisation for all groups. HR=Cox proportional hazard ratio. CEA=carotid endarterectomy, CAS=carotid artery stenting, BMT=best medical treatment.

Les controverses

L'athéromatose n'est pas une maladie propre à notre civilisation

Atherosclerosis across 4000 years of human history: the Horus study of four ancient populations

Randall C Thompson, Adel H Allam, Guido P Lombardi, L Samuel Wann, M Linda Sutherland, James D Sutherland, Muhammad Al-Tohamy Soliman, Bruno Frohlich, David T Mininberg, Janet M Monge, Clide M Vallodolid, Samantha L Cox, Gomaa Abd el-Maksoud, Ibrahim Badr, Michael I Miyamoto, Abd el-Halim Nur el-din, Jagat Narula, Caleb E Finch, Gregory S Thomas

Summary

Background Atherosclerosis is thought to be a disease of modern human beings and related to contemporary lifestyles. However, its prevalence before the modern era is unknown. We aimed to evaluate preindustrial populations for atherosclerosis.

Methods We obtained whole body CT scans of 137 mummies from four different geographical regions or populations spanning more than 4000 years. Individuals from ancient Egypt, ancient Peru, the Ancestral Puebloans of southwest America, and the Unangan of the Aleutian Islands were imaged. Atherosclerosis was regarded as definite if a calcified plaque was seen in the wall of an artery and probable if calcifications were seen along the expected course of an artery.

Blood cholesterol and vascular mortality by age, sex, and blood pressure: a meta-analysis of individual data from 61 prospective studies with 55 000 vascular deaths

*Prospective Studies Collaboration**

Summary

Background Age, sex, and blood pressure could modify the associations of total cholesterol (and its main two fractions, HDL and LDL cholesterol) with vascular mortality. This meta-analysis combined prospective studies of vascular mortality that recorded both blood pressure and total cholesterol at baseline, to determine the joint relevance of these two risk factors.

Lancet 2007; 370: 1829–39

See [Comment](#) page 1803

*Collaborators listed in full at end of paper

	Person-years (thousands)	IHD	Ischaemic stroke	Haemorrhagic stroke	Total stroke*	Other vascular
40–49 years	3442	1309	47	154	412	388
50–59 years	4140	5561	178	466	1370	1387

* Includes 869 deaths from subarachnoid haemorrhage (not included with haemorrhagic stroke) and 5960 deaths in which the type of stroke was unknown or not reported.

Table 1: Person-years and numbers of deaths attributed to IHD, stroke, and other vascular causes, by age at risk

Figure 1: IHD mortality (33744 deaths) versus usual total cholesterol

(A) Age-specific associations. (B) Age-specific and sex-specific hazard ratios for 1 mmol/L lower usual total cholesterol. Hazard ratios on the left are plotted on a floating absolute scale of risk (so each log hazard ratio has an appropriate variance assigned to it). The slopes of the age-specific lines on the left are given on the right, subdivided by sex. Each square (left or right) has an area inversely proportional to the variance of the log of the hazard ratio that it represents.

Figure 3: IHD mortality (3020 deaths) versus usual (A) HDL cholesterol; (B) non-HDL cholesterol; and (C) total/HDL cholesterol
 Age-specific associations. Conventions as in figure 1. HR denotes the hazard ratio (95% CI) per 1.33 lower total/HDL cholesterol (see also webfigure 5).

Figure 4: Stroke mortality (11 663 deaths) versus usual total cholesterol

(A) age-specific associations for total stroke; and (B) subtype-specific and age-specific hazard ratios for 1 mmol/L lower usual total cholesterol. Conventions as in figure 1. SAH=subarachnoid haemorrhage.

Figure 6: Stroke mortality (914 deaths) versus usual (A) HDL cholesterol; (B) non-HDL cholesterol; and (C) total/HDL cholesterol

Age-specific associations. Conventions as in figures 1 and 3. HR denotes the hazard ratio per 1.33 lower total/HDL cholesterol.

Interprétation

- Le cholestérol total a été associé positivement à la mortalité par IDM chez les patients d'âge moyen et avancé et à tous les niveaux de pression artérielle.
- L'absence d'association positive indépendante du cholestérol avec la mortalité par accident vasculaire cérébral, en particulier chez les personnes âgées ou à pression artérielle élevée, est inexplicquée et appelle de nouvelles recherches.
- Néanmoins, des essais randomisés ont montré de manière concluante que les statines réduisent considérablement non seulement le taux d'événements coronariens, mais également le taux d'accidents vasculaires cérébraux totaux chez les patients de tous âges et de toute pression artérielle.

BMJ Open Lack of an association or an inverse association between low-density-lipoprotein cholesterol and mortality in the elderly: a systematic review

Uffe Ravnskov,¹ David M Diamond,² Rokura Hama,³ Tomohito Hamazaki,⁴ Björn Hammar skjöld,⁵ Niamh Hynes,⁶ Malcolm Kendrick,⁷ Peter H Langsjoen,⁸ Aseem Malhotra,⁹ Luca Mascitelli,¹⁰ Kilmer S McCully,¹¹ Yoichi Ogushi,¹² Harumi Okuyama,¹³ Paul J Rosch,¹⁴ Tore Schersten,¹⁵ Sherif Sultan,⁶ Ralf Sundberg¹⁶

Un taux accru de cholestérol transporté par les LDL n'est pas associé à une mortalité globale et cardiovasculaire accrue chez le sujet âgé de 60 ans ou plus

Cette synthèse méthodique n'a pas établi de lien entre un taux élevé de LDL-C et la mortalité cardiovasculaire ou globale chez des sujets âgés de 60 ans ou plus. Au contraire plusieurs études épidémiologiques vont dans le sens d'une relation inverse. Comme les auteurs l'argumentent très bien, la théorie du cholestérol s'avère en conflit avec beaucoup de critères de Bradford Hill. De nouvelles recherches sont nécessaires pour élucider les causes de l'athéromatose et surtout les recommandations de pratique clinique sur la gestion du risque cardiovasculaire doivent être revues à la lumière de toutes les données suggérant que le rôle de l'hypercholestérolémie a été exagéré ainsi que le bénéfice des traitements hypocholestérolémiants en tant qu'agissant sur le taux de cholestérol. Les effets positifs de certains de ces médicaments rapportés relèvent probablement d'autres mécanismes d'action.

Critères de Bradford et Hill

Une simple corrélation n'est pas synonyme de causalité.

1. **Force de l'association** (plus l'ampleur des effets liés à l'association sont larges, plus un lien causal est probable, même si un faible effet n'implique pas une absence de lien de causalité)
2. **Stabilité de l'association** (sa répétition dans le temps et l'espace)
3. **Cohérence** (les mêmes observations sont réalisées dans différentes populations)
4. **Spécificité** (une cause produit un effet particulier dans une population particulière en l'absence d'autres explications)
5. **Relation temporelle** (temporalité). Les causes doivent précéder les conséquences.
6. **Relation dose-effet** (une plus large dose mène à un plus large effet).
7. **Plausibilité** (plausibilité biologique, possibilité d'expliquer les mécanismes impliqués).
8. **Preuve expérimentale** (chez l'animal ou chez l'homme).
9. **Analogie** (possibilité d'explications alternatives).

Main Air Pollutants and Myocardial Infarction

A Systematic Review and Meta-analysis

Context Short-term exposure to high levels of air pollution may trigger myocardial infarction (MI), but this association remains unclear.

Objective To assess and quantify the association between short-term exposure to major air pollutants (ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, and particulate matter $\leq 10 \mu\text{m}$ [PM_{10}] and $\leq 2.5 \mu\text{m}$ [$\text{PM}_{2.5}$] in diameter) on MI risk.

Data Sources EMBASE, Ovid MEDLINE in-process and other nonindexed citations, and Ovid MEDLINE (between 1948 and November 28, 2011), and EBM Reviews–Cochrane Central Register of Controlled Trials and EBM Reviews–Cochrane Database of Systematic Reviews (between 2005 and November 28, 2011) were searched for a combination of keywords related to the type of exposure (air pollution, ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10} , and $\text{PM}_{2.5}$) and to the type of outcome (MI, heart attack, acute coronary syndrome).

Study Selection Two independent reviewers selected studies of any study design and in any language, using original data and investigating the association between short-term exposure (from up to 7 days) to 4 common air pollutants and subsequent MI.

A Ozone analysis

Conclusions

Tous les principaux polluants atmosphériques, à l'exception de l'ozone, ont été associés de manière significative à une **augmentation du risque d'IDM** :

- monoxyde de carbone: 1,048; IC à 95%, 1,026 à 1,070
- dioxyde d'azote: 1,011; IC à 95%, 1,006 à 1,016
- dioxyde de soufre : 1,010; IC à 95%, 1,003 à 1,017
- PM10: 1,006; IC à 95%, 1,002 à 1,009
- PM2,5: 1,025; IC à 95%, 1,015 à 1,036)
- Ozone: 1,003 (IC à 95%, 0,997-1,010; $p = 0,36$).

Les analyses de sous-groupes ont fourni des résultats comparables à ceux de l'ensemble des analyses.

Les fractions attribuables à la population variaient entre 0,6% et 4,5%, selon le polluant.

Note: ref = reference group. *Adjusted for age, sex and cohort. †Defined as having a job with high demands (a job-demand mean score above the study-specific median) and low control (a job-control mean score below the study-specific median); “no job strain” was denoted by all other combinations of demands and control. ‡Smoking, heavy drinking, physical inactivity and obesity. 0 lifestyle risk factors = healthy lifestyle, 1 risk factor = moderately unhealthy lifestyle, 2–4 risk factors = unhealthy lifestyle.				

Figure 1: Associations of lifestyle risk factors and job strain with risk of coronary artery disease after adjustment for age, sex and cohort. Values greater than 1.0 indicate an increased risk of incident coronary artery disease. CI = confidence interval. *0 risk factors = healthy lifestyle, 1 risk factor = moderately unhealthy lifestyle and ≥ 2 risk factors = unhealthy lifestyle.

Conclusion

Dans cette méta-analyse des données regroupées provenant d'études de cohortes prospectives, **le risque de maladie coronarienne était le plus élevé parmi les participants ayant signalé des tensions professionnelles et un mode de vie malsain**; ceux qui éprouvaient des difficultés au travail et qui menaient un mode de vie sain avaient environ la moitié du taux de cette maladie.

Ces données d'observation suggèrent qu'un mode de vie sain pourrait réduire considérablement le risque de maladie coronarienne chez les personnes souffrant de contraintes professionnelles. En plus du counselling sur le stress, les cliniciens pourraient envisager de prêter une attention accrue aux facteurs de risque du mode de vie des patients signalant des tensions professionnelles.

Horaires de travail longs (≥ 55 h par semaine vs 35 – 40 h)

Long working hours and risk of coronary heart disease and stroke: a systematic review and meta-analysis of published and unpublished data for 603 838 individuals

Summary

Background Long working hours might increase the risk of cardiovascular disease, but prospective evidence is scarce, imprecise, and mostly limited to coronary heart disease. We aimed to assess long working hours as a risk factor for incident coronary heart disease and stroke.

Methods We identified published studies through a systematic review of PubMed and Embase from inception to

Environnements précoces, origines précoces de la santé et des maladies

Marie-Noël Bruné Drisse

ÉDITORIAL

> Les enfants d'aujourd'hui habitent un monde en pleine évolution. La globalisation et l'industrialisation offrent aux populations des opportunités dans de nombreux domaines, mais elles nous exposent en parallèle à des risques nouveaux. Pendant ces dernières décennies, les connaissances scientifiques ont connu des avancées rapides. Ainsi, les recherches réalisées autour du concept de la DOHaD (origines développementales de la santé et des maladies) ont permis de mettre en évidence la vulnérabilité toute particulière des enfants, depuis leur conception et pendant les premières années de vie, aux facteurs de risque chimiques, biologiques et physiques présents dans leurs environnements, mais

les pays à revenus faibles ou intermédiaires, le coût de l'exposition et de son impact représentait 1,20 % du produit intérieur brut (PIB) mondial en 2011 [2].

Les études mettent également en évidence un lien entre l'exposition prénatale à la pollution de l'air et le petit poids de naissance et le développement cognitif chez l'enfant. Les périodes de développement, et donc de vulnérabilité, pourraient ainsi représenter des périodes de prévention au cours desquelles l'impact de nos interventions serait le plus efficace. Un renforcement de nos politiques environnementales et une adaptation des

Body-Mass Index in 2.3 Million Adolescents and Cardiovascular Death in Adulthood

Gilad Twig, M.D., Ph.D., Gal Yaniv, M.D., Ph.D., Hagai Levine, M.D., M.P.H., Adi Leiba, M.D., M.H.A., Nehama Goldberger, M.Sc., Estela Derazne, M.Sc., Dana Ben-Ami Shor, M.D., Dorit Tzur, M.B.A., Arnon Afek, M.D., M.H.A., Ari Shamiss, M.D., M.P.H., Ziona Haklai, M.A., and Jeremy D. Kark, M.D., Ph.D.

ABSTRACT

BACKGROUND

In light of the worldwide increase in childhood obesity, we examined the association between body-mass index (BMI) in late adolescence and death from cardiovascular causes in adulthood.

METHODS

We grouped data on BMI, as measured from 1967 through 2010 in 2.3 million Israeli adolescents (mean age, 17.3 ± 0.4 years), according to age- and sex-specific percentiles from the U.S. Centers for Disease Control and Prevention. Primary outcomes were the number of deaths attributed to coronary heart disease, stroke, sudden death from an unknown cause, or a combination of all three categories (total cardiovascular causes) by mid-2011. Cox proportional-hazards models were used.

RESULTS

During 42,297,007 person-years of follow-up, 2918 of 32,127 deaths (9.1%) were from cardiovascular causes, including 1497 from coronary heart disease, 528 from stroke, and 893 from sudden death. On multivariable analysis, there was a graded increase in the risk of death from cardiovascular causes and all causes that started among participants in the group that was in the 50th to 74th percentiles of BMI (i.e., within the accepted normal range). Hazard ratios in the obese group (≥ 95 th percentile for BMI), as compared with the reference group in the 5th to 24th percentiles, were 4.9 (95% confidence interval [CI], 3.9 to 6.1) for death from coronary

Conclusion

Un IMC compris entre le 50^{ème} et le 74^{ème} percentile, dans la fourchette normale acceptée, à l'adolescence est associé à une augmentation de la mortalité cardiovasculaire et de toutes causes confondues au cours des 40 années de suivi.

Le surpoids et l'obésité sont fortement associés à une mortalité cardiovasculaire accrue à l'âge adulte.

ABSTRACT

OBJECTIVE

To examine the cardiovascular risks of diclofenac initiation compared with initiation of other traditional non-steroidal anti-inflammatory drugs, initiation of paracetamol, and no initiation.

DESIGN

Series of 252 nationwide cohort studies, each mimicking the strict design criteria of a clinical trial (emulated trial design).

SETTING

Danish, nationwide, population based health registries (1996-2016).

PARTICIPANTS

Individuals eligible for inclusion were all adults without malignancy; schizophrenia; dementia; or cardiovascular, kidney, liver, or ulcer diseases (that is, with low baseline risk). The study included 1 370 832

RESULTS

The adverse event rate among diclofenac initiators increased by 50% compared with non-initiators (incidence rate ratio 1.5, 95% confidence interval 1.4 to 1.7), 20% compared with paracetamol or ibuprofen initiators (both 1.2, 1.1 to 1.3), and 30% compared with naproxen initiators (1.3, 1.1 to 1.5). The event rate for diclofenac initiators increased for each component of the combined endpoint (1.2 (1.1 to 1.4) for atrial fibrillation/flutter, 1.6 (1.3 to 2.0) for ischaemic stroke, 1.7 (1.4 to 2.0) for heart failure, 1.9 (1.6 to 2.2) for myocardial infarction, and 1.7 (1.4 to 2.1) for cardiac death) as well as for low doses of diclofenac, compared with non-initiators. Although the relative risk of major adverse cardiovascular events was highest in individuals with low or moderate baseline risk (that is, diabetes mellitus), the absolute risk was highest in individuals with high baseline risk (that is, individuals with high baseline risk of cardiovascular events).

Fig 2 | Cardiovascular risks at 30 days associated with diclofenac initiation compared with no NSAID initiation and initiation of paracetamol, ibuprofen, or naproxen. NSAID=non-steroidal anti-inflammatory drug; MACE=major adverse cardiovascular event

Fig 4 | Risk of major adverse cardiovascular events after diclofenac initiation according to baseline cardiovascular risk. NSAID=non-steroidal anti-inflammatory drug

Fig 5 | Risk of major adverse cardiovascular events comparing initiation of low and high dose diclofenac with no NSAID initiation or initiation of paracetamol, ibuprofen, or naproxen. NSAID=non-steroidal anti-inflammatory drug

Conclusion

Cette étude fournit une vue d'ensemble du spectre et de l'ampleur des risques cardiovasculaires liés à l'initiation du diclofénac. Elle a également montré que les initiateurs du diclofénac présentaient un risque hémorragique gastro-intestinal supérieur similaire à celui des initiateurs du naproxène et plus de deux fois plus de risques que les initiateurs d'ibuprofène. Le traitement de la douleur et de l'inflammation avec des AINS peut être intéressant pour certains patients afin d'améliorer leur qualité de vie malgré les effets secondaires potentiels. Compte tenu de ses risques cardiovasculaires et gastro-intestinaux, il n'est guère justifié d'instaurer un traitement par le diclofénac avant les autres AINS classiques.

Previous studies have suggested that the obstructive sleep apnea syndrome may be an important risk factor for stroke. It has not been determined, however, whether the syndrome is independently related to the risk of stroke or death from any cause after adjustment for other risk factors, including hypertension.

METHODS

In this observational cohort study, consecutive patients underwent polysomnography, and subsequent events (strokes and deaths) were verified. The diagnosis of the obstructive sleep apnea syndrome was based on an apnea–hypopnea index of 5 or higher (five or more events per hour); patients with an apnea–hypopnea index of less than 5 served as the comparison group. Proportional-hazards analysis was used to determine the independent effect of the obstructive sleep apnea syndrome on the composite outcome of stroke or death from any cause.

Table 3. Trend Analysis for the Relationship between Increased Severity of the Obstructive Sleep Apnea Syndrome and the Composite Outcome of Stroke or Death from Any Cause (N=1022).*

Severity of Syndrome	Stroke or Death		Mean Follow-up Period yr	Hazard Ratio (95% CI)
	No. of Events	No. of Patients		
AHI ≤ 3 (reference score)	13	271	3.08	1.00
AHI 4–12	21	258	3.06	1.75 (0.88–3.49)
AHI 13–36	20	243	3.09	1.74 (0.87–3.51)
AHI >36	34	250	2.78	3.30 (1.74–6.26)

* P=0.005 by the chi-square test for linear trend. AHI denotes apnea–hypopnea index, and CI confidence interval.

Long-term cardiovascular outcomes of COVID-19

Yan Xie ^{1,2,3}, Evan Xu ^{1,4}, Benjamin Bowe^{1,2} and Ziyad Al-Aly ^{1,2,5,6,7} 

The cardiovascular complications of acute coronavirus disease 2019 (COVID-19) are well described, but the post-acute cardiovascular manifestations of COVID-19 have not yet been comprehensively characterized. Here we used national healthcare databases from the US Department of Veterans Affairs to build a cohort of 153,760 individuals with COVID-19, as well as two sets of control cohorts with 5,637,647 (contemporary controls) and 5,859,411 (historical controls) individuals, to estimate risks and 1-year burdens of a set of pre-specified incident cardiovascular outcomes. We show that, beyond the first 30 d after infection, individuals with COVID-19 are at increased risk of incident cardiovascular disease spanning several categories, including cerebrovascular disorders, dysrhythmias, ischemic and non-ischemic heart disease, pericarditis, myocarditis, heart failure and thromboembolic disease. These risks and burdens were evident even among individuals who were not hospitalized during the acute phase of the infection and increased in a graded fashion according to the care setting during the acute phase (non-hospitalized, hospitalized and admitted to intensive care). Our results provide evidence that the risk and 1-year burden of cardiovascular disease in survivors of acute COVID-19 are substantial. Care pathways of those surviving the acute episode of COVID-19 should include attention to cardiovascular health and disease.

Fig. 1 | Flowchart of cohort construction. Cohort construction for COVID-19 group (blue), contemporary control group (yellow) and historical control group (orange). Comparisons between groups are presented in green.

Fig. 3 | Risks and 12-month burdens of incident post-acute COVID-19 composite cardiovascular outcomes compared with the contemporary control cohort. Composite outcomes consisted of cerebrovascular

MACE : major adverse cardiovascular event (mortality, stroke and myocardial infarction)

Fig. 6 | Risks and 12-month burdens of incident post-acute COVID-19 composite cardiovascular outcomes compared with the contemporary control cohort by care setting of the acute infection. Risks and burdens

Conclusions

- Par rapport aux contrôles « contemporains », les personnes ayant eu le Covid-19 avaient un surrisque (hazard ratio : 1,63) de survenue d'événements cardiovasculaires dans l'année suivant l'infection.
- Le surrisque d'événement cardiovasculaire était d'autant plus important que la sévérité du Covid avait été grande.
- Le surrisque persiste chez les patients ayant eu des épisodes non graves.
- Cette augmentation du risque CV était observée dans tous les sous-groupes, quels que soient les autres facteurs de risque cardiovasculaire connus.
- Des résultats similaires ont été obtenus en comparant la cohorte Covid au groupe contrôle « historique », soulignant que l'excès de risque existe indépendamment de la période analysée.
- Attention : cette étude a inclus des personnes infectées lors de la première année pandémique et la période considérée précède la mise à disposition des vaccins
